

**1. Intro.** Find placements of at most  $r$  queens on an  $m \times n$  board, so that (i) no row, column, or diagonal contains three queens; and (ii) adding any new queen would violate condition (i).

(This problem was mentioned in Gardner’s column on October 1976, and discussed by Cooper, Pikhurko, Schmitt, and Warrington in *AMM* **121** (2014), 213–221. The latter authors said they did a “brute force search” to show unsatisfiability for  $m = n = r = 11$ , and it took 900 hours on 3-gigahertz computers. Naturally I wondered if SAT methods would be better.)

Variable  $i.j$  means there’s a queen on cell  $(i, j)$ . Variable  $Ri$  means there are two queens in row  $i$ . Variable  $Cj$  means there are two queens in column  $j$ . Variable  $Ad$  means there are two queens in the diagonal  $i + j - 1 = d$ , for  $1 \leq d < m + n$ . Variable  $Dd$  means there are two queens in the diagonal  $i - j + n = d$ , for  $1 \leq d < m + n$ .

The constraints for condition (i) are obvious. For example, there are  $\binom{n}{3}$  constraints for each row, saying that no three queens are present in that row.

The constraints for condition (ii) are that, if no queen is in  $(i, j)$ , then either its  $R$  or  $C$  or  $A$  or  $D$  variable is true.

(Actually I decided to use a more complex naming scheme for the  $R$ ,  $C$ ,  $A$ ,  $D$  variables; see below.)

```
#define max_m_plus_n 100    /* upper bound on m + n */
#define max_mn 10000       /* upper bound on mn */
#include <stdio.h>
#include <stdlib.h>
int m, n, r;               /* command-line parameters */
char name[max_m_plus_n][8];
int ap[max_m_plus_n], dp[max_m_plus_n];
int count[2 * max_mn];     /* used for the cardinality constraints */
<Subroutine 4>;
main(int argc, char *argv[])
{
    register int i, j, k, mn, p, t, tl, tr, jl, jr;
    <Process the command line 2>;
    for (i = 1; i ≤ m; i++) <Forbid three in row i 3>;
    for (j = 1; j ≤ n; j++) <Forbid three in column j 5>;
    for (k = 1; k < m + n; k++) <Forbid three in diagonal Ak 6>;
    for (k = 1; k < m + n; k++) <Forbid three in diagonal Dk 7>;
    <Generate the clauses for condition (ii) 8>;
    <Generate clauses to ensure at most r queens 9>;
}
```

```

2.  ⟨ Process the command line 2 ⟩ ≡
    if (argc ≠ 4 ∨ sscanf(argv[1], "%d", &m) ≠ 1 ∨ sscanf(argv[2], "%d", &n) ≠ 1 ∨ sscanf(argv[3], "%d", &r) ≠ 1)
    {
        fprintf(stderr, "Usage: %s m n r\n", argv[0]);
        exit(-1);
    }
    if (m ≡ 1 ∨ n ≡ 1) {
        fprintf(stderr, "m and n must be 2 or more!\n");
        exit(-2);
    }
    if (m + n ≥ max_m_plus_n) {
        fprintf(stderr, "m+n must be less than %d!\n", max_m_plus_n);
        exit(-3);
    }
    mn = m * n;
    if (mn ≥ max_mn) {
        fprintf(stderr, "m*n must be less than %d!\n", max_mn);
        exit(-3);
    }
    printf("~sat-nothree %d %d %d\n", m, n, r);

```

This code is used in section 1.

**3.** Sinz's clauses for the cardinality constraints work well for this application. In row  $i$ , there are variables  $iRj$  and  $iRj'$  for  $1 \leq j < n$ , meaning that  $x_{i1} + \dots + x_{ij} \geq 1$  and  $x_{i1} + \dots + x_{i(j+1)} \geq 2$ , respectively. The variable  $iRn - 1'$  corresponds to what was called  $Ri$  above.

```

⟨ Forbid three in row i 3 ⟩ ≡
{
    for (j = 1; j ≤ n; j++) sprintf(name[j - 1], "%d.%d", i, j);
    forbid(i, 'R', n);
}

```

This code is used in section 1.

4.  $\langle \text{Subroutine 4} \rangle \equiv$   
**void forbid**(**int** *i*, **char** *t*, **int** *n*)  
{  
  **register** *j*;  
  **for** (*j* = 1; *j* < *n*; *j*++) {  
    **if** (*j* < *n* - 1) {  
      printf("%d%c%d%d%c%d\n", *i*, *t*, *j*, *i*, *t*, *j* + 1);  
      printf("%d%c%d' %d%c%d'\n", *i*, *t*, *j*, *i*, *t*, *j* + 1);  
      printf("%s%d%c%d'\n", *name*[*j* + 1], *i*, *t*, *j*);  
    }  
    printf("%s%d%c%d\n", *name*[*j* - 1], *i*, *t*, *j*);  
    printf("%d%c%d' %s", *i*, *t*, *j*, *name*[*j* - 1]);  
    **if** (*j* > 1) printf("%d%c%d\n", *i*, *t*, *j* - 1);  
    **else** printf("\n");  
    printf("%s%d%c%d' %d%c%d'\n", *name*[*j*], *i*, *t*, *j*, *i*, *t*, *j*);  
    printf("%d%c%d' %d%c%d'\n", *i*, *t*, *j*, *i*, *t*, *j*);  
    printf("%d%c%d' %s", *i*, *t*, *j*, *name*[*j*]);  
    **if** (*j* > 1) printf("%d%c%d'\n", *i*, *t*, *j* - 1);  
    **else** printf("\n");  
  }  
}

This code is used in section 1.

5.  $\langle \text{Forbid three in column } j \text{ 5} \rangle \equiv$   
{  
  **for** (*i* = 1; *i* ≤ *m*; *i*++) *sprintf*(*name*[*i* - 1], "%d.%d", *i*, *j*);  
  *forbid*(*j*, 'C', *m*);  
}

This code is used in section 1.

6.  $\langle \text{Forbid three in diagonal } A_k \text{ 6} \rangle \equiv$   
{  
  *p* = 0;  
  **for** (*i* = 1; *i* ≤ *m*; *i*++) {  
    *j* = *k* + 1 - *i*;  
    **if** (*j* ≥ 1 ∧ *j* ≤ *n*) {  
      *sprintf*(*name*[*p*], "%d.%d", *i*, *j*);  
      *p*++;  
    }  
  }  
  *forbid*(*k*, 'A', *p*);  
  *ap*[*k*] = *p*;  
}

This code is used in section 1.

7.  $\langle \text{Forbid three in diagonal } D_k \text{ 7} \rangle \equiv$

```
{
  p = 0;
  for (i = 1; i ≤ m; i++) {
    j = i + n - k;
    if (j ≥ 1 ∧ j ≤ n) {
      sprintf(name[p], "%d.%d", i, j);
      p++;
    }
  }
  forbid(k, 'D', p);
  dp[k] = p;
}
```

This code is used in section 1.

8.  $\langle \text{Generate the clauses for condition (ii) 8} \rangle \equiv$

```
for (i = 1; i ≤ m; i++)
  for (j = 1; j ≤ n; j++) {
    printf("%d.%d.%dR%d'_%dC%d'", i, j, i, n - 1, j, m - 1);
    if (ap[i + j - 1] > 1) printf("_%dA%d'", i + j - 1, ap[i + j - 1] - 1);
    if (dp[i - j + n] > 1) printf("_%dD%d'", i - j + n, ap[i - j + n] - 1);
    printf("\n");
  }
```

This code is used in section 1.

9. The clauses of SAT-THRESHOLD-BB are used for the  $\leq r$  constraint.

$\langle \text{Generate clauses to ensure at most } r \text{ queens 9} \rangle \equiv$   
 $\langle \text{Build the complete binary tree with } mn \text{ leaves 10} \rangle;$   
 for ( $i = mn - 2$ ;  $i$ ;  $i--$ )  $\langle \text{Generate the clauses for node } i \text{ 11} \rangle;$   
 $\langle \text{Generate the clauses at the root 12} \rangle;$

This code is used in section 1.

10. The tree has  $2mn - 1$  nodes, with 0 as the root; the leaves start at node  $mn - 1$ . Nonleaf node  $k$  has left child  $2k + 1$  and right child  $2k + 2$ . Here we simply fill the *count* array.

$\langle \text{Build the complete binary tree with } mn \text{ leaves 10} \rangle \equiv$   
 for ( $k = mn + mn - 2$ ;  $k \geq mn - 1$ ;  $k--$ )  $\text{count}[k] = 1$ ;  
 for ( $k \geq 0$ ;  $k--$ )  $\text{count}[k] = \text{count}[k + k + 1] + \text{count}[k + k + 2]$ ;  
 if ( $\text{count}[0] \neq mn$ )  $\text{fprintf}(\text{stderr}, "I'm\_totally\_confused.\n")$ ;

This code is used in section 9.

**11.** If there are  $t$  leaves below node  $i$ , we introduce  $k = \min(r, t)$  variables  $B_{i+1}.j$  for  $1 \leq j \leq k$ . This variable is 1 if (but not only if) at least  $j$  of those leaf variables are true. If  $t > r$ , we also assert that no  $r + 1$  of those variables are true.

**#define**  $xbar(k)$  `printf("%d.%d", (((k) - mn + 1)/n) + 1, (((k) - mn + 1) % n) + 1)`

⟨Generate the clauses for node  $i$  11⟩  $\equiv$

```
{
  t = count[i], tl = count[i + i + 1], tr = count[i + i + 2];
  if (t > r + 1) t = r + 1;
  if (tl > r) tl = r;
  if (tr > r) tr = r;
  for (jl = 0; jl ≤ tl; jl++)
    for (jr = 0; jr ≤ tr; jr++)
      if ((jl + jr ≤ t) ∧ (jl + jr) > 0) {
        if (jl) {
          if (i + i + 1 ≥ mn - 1) xbar(i + i + 1);
          else printf("~B%d.%d", i + i + 2, jl);
        }
        if (jr) {
          printf("_");
          if (i + i + 2 ≥ mn - 1) xbar(i + i + 2);
          else printf("~B%d.%d", i + i + 3, jr);
        }
        if (jl + jr ≤ r) printf("_B%d.%d\n", i + 1, jl + jr);
        else printf("\n");
      }
}
```

This code is used in section 9.

**12.** Finally, we assert that at most  $r$  of the  $x$ 's aren't true, by implicitly asserting that the (nonexistent) variable  $B_{1.r+1}$  is false.

⟨Generate the clauses at the root 12⟩  $\equiv$

```
tl = count[1], tr = count[2];
if (tl > r) tl = r;
for (jl = 1; jl ≤ tl; jl++) {
  jr = r + 1 - jl;
  if (jr ≤ tr) {
    if (1 ≥ mn - 1) xbar(1);
    else printf("~B2.%d", jl);
    printf("_");
    if (2 ≥ mn - 1) xbar(2);
    else printf("~B3.%d", jr);
    printf("\n");
  }
}
```

This code is used in section 9.
